

A detailed illustration of a Red Porgy (Lutjanus campechanus) fish, shown in profile facing left. The fish has a robust, deep-bodied shape. Its coloration is primarily reddish-brown with lighter, silvery-gold highlights on the upper half of its body. A prominent, spiny dorsal fin runs along the top of its back. The head is large with a prominent, slightly protruding lower jaw. The eyes are large and dark. The pectoral fins are visible on the sides, and the pelvic and anal fins are located ventrally. The tail is deeply forked. The overall appearance is that of a healthy, mature specimen.

81 **Executive Summary**

executive-summary

82 **Stock**

stock

83 This assessment reports the status of the Pacific ocean perch (*Sebastes alutus*) species off
84 rockfish off the U.S. West Coast from Northern California to the Canadian Border using
85 data through 2017. Pacific ocean perch are most abundant in the Gulf of Alaska and have
86 observed off of Japan, in the Bering Sea, and south to Baja California, although they are
87 sparse south of Oregon and rare in southern California. Composition data indicate that
88 good recruitment years coincide in Oregon and Washington. To date, no significant genetic
89 differences have been found in the range covered by this assessment.

90 **Landings**

landings

91 The first year that harvest of Pacific ocean perch exceeded 1 mt off the U.S. West Coast
92 first occurred in 1929. Catches ramped up in the 1940s with large removals in Washington
93 waters. During the 1950s the removals primarily occurred in Oregon waters with catches from
94 Washington declining following the 1940s. The largest removals in 1966-1968 were largely a
95 result of harvest by foreign vessels. The fishery proceeded with more moderate removals ranging
96 between 1,200 to 2,600 metric tons per year between 1969 to 1980. Removals generally
97 declined from 1981 to 1994 to between 1,000 and 1,700 metric tons per year. Pacific ocean
98 perch was declared overfished in 1999 resulting in large reduction in harvest in recent years
99 since the declaration.

Table a: Landings (mt) for the past 10 years for Pacific ocean perch by fleet.

| Year | California | Oregon | Washington | At-sea-hake | Survey | tab:Exec_catch |
|------|------------|--------|------------|-------------|--------|----------------|

Data and Assessment

data-and-assessment

This a new full assessment for Pacific ocean perch which was last assessed in 2011. In this assessment, all aspects of the model including catches, data, and modelling assumptions were re-evaluated as much as possible. The assessment was conducted using the length- and age-structured modeling software Stock Synthesis (version 3.30). The coastwide population was modeled assuming separate growth and mortality parameters for each sex (a two-sex model) from 1892 to 2017, and forecasted beyond 2017.

Stock Biomass

stock-biomass

Include: trends and current levels relative to virgin or historic levels, description of uncertainty-include table for last 10 years and graph with long term estimates.

Spawning output Figure: Figure [b](#)

Spawning output Table(s): Table [b](#)

Relative depletion Figure: Figure [c](#)

Example text (remove Models 2 and 3 if not needed - if using, remove the # in-line comments!!!)
The estimated relative depletion level (spawning output relative to unfished spawning output) of the the base-case model in 2017 is 33.9% (~95% asymptotic interval: $\pm 23.3\%$ -44.6%) (Figure [c](#)).

Table b: Recent trend in beginning of the year spawning output and depletion for the Base model for Pacific ocean perch.

| tab:SpawningDeplete_mod1 | | | | |
|--------------------------|-----------------------------------|------------------------------|------------------------|------------------------------|
| Year | Spawning Output (billion eggs) | ~ 95% confidence interval | Estimated depletion | ~ 95% confidence interval |
| 2008 | 8344.00 | 4420 - 12268 | 0.15 | 0.103 - 0.197 |

| 2013 | 30.00 | 17 - 53 | |
| 2014 | 2.00 | 1 - 7 | |
| 2015 | 4.00 | 1 - 13 | |
| 2016 | 4.00 | 1 - 15 | |
| 2017 | 5.00 | 2 - 12 | |

Figure d: Time series of estimated Pacific ocean perch recruitments for the base-case model with 95% confidence or credibility intervals. `fig:Recruits_all`

Exploitation status

exploitation-status

Include: exploitation rates (i.e., total catch divided by exploitable biomass, or the annual SPR harvest rate) include a table with the last 10 years of data and a graph showing the trend in fishing mortality relative to the target (y-axis) plotted against the trend in biomass relative to the target (x-axis).

Exploitation Tables: Table d, Table ??, Table ?? Exploitation Figure: Figure e).

A summary of Pacific ocean perch exploitation histories for base model is provided as Figure f.

Table d: Recent trend in spawning potential ratio and exploitation for Pacific ocean perch in the Base model. Fishing intensity is $(1-SPR)$ divided by 50% (the SPR target) and exploitation is F divided by F_{SPR} .

| Year | Fishing intensity | ~ 95% confidence interval | Exploitation rate | tab:SPR_Exploit_mod1 ~ 95% confidence |
|------|----------------------|------------------------------|----------------------|--|
| | | | | interval |
| 2007 | 0.377 | 0.229 - 0.524 | 0.008 | 0.005 - 0.012 |
| 2008 | 0.396 | 0.236 - 0.555 | 0.009 | 0.005 - 0.013 |
| 2009 | 0.413 | 0.245 - 0.580 | 0.010 | 0.005 - 0.015 |
| 2010 | 0.396 | 0.234 - 0.557 | 0.009 | 0.005 - 0.014 |
| 2011 | 0.165 | 0.092 - 0.238 | 0.003 | 0.001 - 0.004 |
| 2012 | 0.153 | 0.085 - 0.221 | 0.002 | 0.001 - 0.003 |
| 2013 | 0.138 | 0.076 - 0.200 | 0.002 | 0.001 - 0.003 |
| 2014 | 0.096 | 0.052 - 0.140 | 0.001 | 0.001 - 0.002 |
| 2015 | 0.107 | 0.058 - 0.155 | 0.002 | 0.001 - 0.002 |
| 2016 | 0.088 | 0.047 - 0.128 | 0.001 | 0.001 - 0.002 |

Figure e: Estimated spawning potential ratio (SPR) for the base-case model. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the $SPR_{50\%}$ harvest rate. The last year in the time series is 2016. fig:SPR_all

Figure f: Phase plot of estimated relative (1-SPR) vs. relative spawning biomass for the base case model. The relative (1-SPR) is (1-SPR) divided by 50% (the SPR target). Relative depletion is the annual spawning biomass divided by the unfished spawning biomass. fig:Phase_all

Ecosystem Considerations

ecosystem-considerations

In this assessment, ecosystem considerations were....

Reference Points

reference-points

Include: management targets and definition of overfishing, including the harvest rate that brings the stock to equilibrium at $B_{40\%}$ (the B_{MSY} proxy) and the equilibrium stock size that results from fishing at the default harvest rate (the F_{MSY} proxy). Include a summary table that compares estimated reference points for SSB, SPR, Exploitation Rate and Yield based on SSBproxy for MSY, SPRproxy for MSY, and estimated MSY values

Write intro paragraph

This stock assessment estimates that Pacific ocean perch in the Base model are below the biomass target, but above the minimum stock size threshold. **Add sentence about spawning output trend.** The estimated relative depletion level for **Model 1** in 2017 is 33.9% (~95% asymptotic interval: $\pm 23.3\%$ -44.6%, corresponding to an unfished spawning output of 18909 billion eggs (~95% asymptotic interval: 9915.73644901456-27901.4635509854 billion eggs) of spawning output in the base model (Table e). Unfished age 3+ biomass was estimated to be 100784 mt in the base case model. The target spawning output based on the biomass target ($SB_{40\%}$) is 22283.9 billion eggs, which gives a catch of 908.2 mt. Equilibrium yield at the proxy F_{MSY} harvest rate corresponding to $SPR_{50\%}$ is 745.4 mt.

Table e: Summary of reference points and management quantities for the base case Base model.

| Quantity | Estimate | tab:Ref_pts_mod1 |
|---|----------|-------------------------|
| | | 95% Confidence Interval |
| Unfished spawning output (billion eggs) | 55709.8 | 44350.8 - 67068.8 |

Research And Data Needs

research-and-data-needs

Include: identify information gaps that seriously impede the stock assessment.

We recommend the following research be conducted before the next assessment:

1. List item No. 1 in the list
2. List item No. 2 in the list, etc.

Rebuilding Projections

rebuilding-projections

Include: reference to the principal results from rebuilding analysis if the stock is overfished. This section should be included in the Final/SAFE version assessment document but is not required for draft assessments undergoing review. See Rebuilding Analysis terms of reference for detailed information on rebuilding analysis requirements.

1 Introduction

introduction

1.1 Basic Information

basic-information

Pacific ocean perch (*Sebastes alutus*) are most abundant in the Gulf of Alaska, and have been observed off of Japan, in the Bering Sea, and south to Baja California, although they are sparse south of Oregon and rare in southern California. While genetic studies have found three populations of Pacific ocean perch off of British Columbia (Seeb and Gunderson 1988, Withler et al. 2001) with, notably, a separate stock off of Vancouver Island, no significant genetic differences have been found in the range covered by this assessment. Pacific ocean perch show dimorphic growth, with females reaching a slightly large size than males. Males and females are equally abundant on rearing grounds at age 1.5.

The Pacific ocean perch population has been modeled as a single stock off of the U.S. West Coast (essentially northern California to the Canadian border, since Pacific ocean perch are seen extremely rarely in central and southern California). Good recruitments show up in size-composition data throughout all portions of this area, which supports the single stock hypothesis. This assessment includes landings and catch data for Pacific ocean perch from the states of Washington, Oregon and California, along with records from foreign fisheries, the at-sea hake fleet, and surveys.

Prior to 1966, the Pacific ocean perch resource off of the northern portion of the U.S. West Coast was harvested almost entirely by Canadian and United States vessels. Harvest was negligible prior to 1940, reached 1,000 mt in 1951, 3,000 mt in 1961 and exceeded 7,000 mt in 1965. Catches increased dramatically after 1965, with the introduction of large distant-water fishing fleets from the Soviet Union and Japan. Both nations employed large factory stern trawlers as their primary method for harvesting Pacific ocean perch. Peak removals by all foreign nations combined are estimated at over 15,000 mt in 1966 and remained over 12,000 mt in 1967. These numbers are based upon a re-analysis of the foreign catch data (Rogers 2003), which focused on deriving a more realistic species composition for catches previously identified only as Pacific ocean perch. Catches declined rapidly following these peak years, and Pacific ocean perch stocks were considered to be severely depleted throughout the Oregon-Vancouver Island region by 1969 (Gunderson 1977, Gunderson et al. 1977). Landed harvest averaged 1,500 mt over the period 1977-94. Landings have continued to decline since 1994, primarily due to more restrictive management.

Prior to 1977, Pacific ocean perch in the northeast Pacific were managed by the Canadian Government in its waters and by the individual states in waters off of the United States. With implementation of the Magnuson Fishery Conservation and Management Act (MFCMA) in 1977, U.S. territorial waters were extended to 200 miles from shore, and primary responsibility for management of the groundfish stocks off Washington, Oregon and California shifted from the states to the Pacific Fishery Management Council (PFMC) and the National Marine Fisheries Service (NMFS). At that time, however, a Fishery Management Plan (FMP) for the

west coast groundfish stocks had not yet been approved. In the interim, the state agencies worked with the PFMC to address conservation issues. In 1981, the PFMC adopted a management strategy to rebuild the depleted Pacific ocean perch stocks to levels that would produce Maximum Sustainable Yield (MSY) within 20 years. On the basis of cohort analysis (Gunderson 1978), the PFMC set Acceptable Biological Catch (ABC) levels at 600 mt for the US portion of the Vancouver INPFC area and 950 mt for the Columbia INPFC area. To implement this strategy, the states of Oregon and Washington each established landing limits for Pacific ocean perch. Trawl trip limits of various forms remained in effect through 2010 (Table 1).

Age estimates for Pacific ocean perch prior to the 1980s were made via surface ageing of otoliths, which misses the very tight annuli at the edge of the otolith once the fish reaches near maximum size. Ages are biased by around age 10-12, and maximum age was estimated to be in the 20s, which lead to an overestimate of the natural mortality rate and the productivity of the stock. Using break and burn methods, Pacific ocean perch have been aged to over 100 years, and we now know that the underlying assumptions of the early models were overly optimistic about productivity. Research surveys have been used to provide fishery-independent information about the abundance, distribution, and biological characteristics of Pacific ocean perch. A coast-wide survey of the rockfish resource was conducted in 1977 (Gunderson and Sample 1980) and was repeated every three years through 2004. The National Marine Fisheries Service (NMFS) coordinated a cooperative research survey of the Pacific ocean perch stocks off Washington and Oregon with the Washington Department of Fisheries (WDFW) and the Oregon Department of Fish and Wildlife (ODFW) in March-May 1979 (Wilkins and Golden 1983). This survey was repeated in 1985. Two slope surveys have been conducted on the west coast in recent years, one using the research vessel Miller Freeman, which ended in 2001, and another ongoing cooperative survey using commercial fishing vessels which began in 1998 as a DTS (Dover sole, thornyhead and sablefish) survey, was expanded to other groundfish in 1999. In 2003, this survey was expanded spatially to include the shelf. This last survey, conducted by the NWFSC, continues to cover depths from 30-700 fathoms (55-1280 meters) on an annual basis.

1.2 Map

map

A map showing the scope of the assessment and depicting boundaries for fisheries or data collection strata is provided in Figure 1.

1.3 Life History

life-history

Include: Important features of life history that affect management (e.g., migration, sexual dimorphism, bathymetric demography).

1.4 Ecosystem Considerations

ecosystem-considerations-1

Include: Ecosystem considerations (e.g., ecosystem role and trophic relationships of the species, habitat requirements/preferences, relevant data on ecosystem processes that may affect stock or parameters used in the stock assessment, and/or cross-FMP interactions with other fisheries). This section should note if environmental correlations or food web interactions were incorporated into the assessment model. The length and depth of this section would depend on availability of data and reports from the IEA, expertise of the STAT, and whether ecosystem factors are informational to contribute quantitative information to the assessment.

1.5 Fishery Information

fishery-information

Include: Important features of current fishery and relevant history of fishery.

1.6 Summary of Management History

summary-of-management-history

Include: Summary of management history (e.g., changes in mesh sizes, trip limits, or other management actions that may have significantly altered selection, catch rates, or discards).

1.7 Management Performance

management-performance-1

Include: Management performance, including a table or tables comparing Overfishing Limit (OFL), Annual Catch Limit (ACL), Harvest Guideline (HG) [CPS only], landings, and catch (i.e., landings plus discard) for each area and year.

Management performance table: (Table f)

A summary of these values as well as other base case summary results can be found in Table i.

1.8 Fisheries off Canada, Alaska, and/or Mexico

fisheries-off-canada-alaska-andor-mexico

Include if necessary.

2 Assessment

assessment

2.1 Data

data

Data used in the Pacific ocean perch assessment are summarized in Figure 2.

A description of each data source is below.

2.1.1 Commercial Fishery Landings

commercial-fishery-landings

Washington

Historical commercial fishery landings of Pacific ocean perch from Washington for the years 1918-1980 were obtained from Theresa Tsou (WDFW) and Phillip Weyland (WDFW). This assessment is the first Pacific ocean perch assessment to include a state provide historical catch reconstruction and hence, the historical catches for Washington vary markedly from those used in the 2011 assessment. Recent landings (1981-2016) were obtained from PacFIN (Pacific Fisheries Information Network (PacFIN) retrieval dated March 3, 2015, Pacific States Marine Fisheries Commission, Portland, Oregon; www.psmfc.org).

Oregon

Historical commercial fishery landings of Pacific ocean perch from Oregon for the years 1892-1986 were obtained from Alison Dauble (ODFW). A description of the methods can be found in (Karnowski et al. 2014). Recent landings (1987-2016) were obtained from PacFIN (Pacific Fisheries Information Network (PacFIN) retrieval dated March 3, 2015, Pacific States Marine Fisheries Commission, Portland, Oregon; www.psmfc.org).

California

Historical commercial fishery landings of Pacific ocean perch were obtained from the on-line database of the California Cooperative Groundfish Survey, also known as CALCOM (128.114.3.187) for the years 1916-1980. A description of the methods can be found in (Ralston et al. 2010). Recent landings (1981-2016) were obtained from PacFIN (Pacific Fisheries Information Network (PacFIN) retrieval dated March 3, 2015, Pacific States Marine Fisheries Commission, Portland, Oregon; www.psmfc.org).

At-sea fishery

Catches of Pacific ocean perch are monitored aboard the vessel by observers in the At-Sea hake Observer program (ASHOP) and were available for the years of 1975-2016. Observers use a spatial sample design, based on weight, to randomly choose a portion of the haul to sample for species composition. For the last decade, this is typically 30-50% of the total

weight. The total weight of the sample is determined by all catch passing over a flow scale. All species other than hake are removed and weighed, by species, on a motion compensated flatbed scale. Observers record the weights of all non-hake species. Non-hake species total weights are expanded in the database by using the proportion of the haul sampled to the total weight of the haul. The catches of non-hake species in unsampled hauls is determined using bycatch rates determined from sampled hauls. Since 2001, more than 97% of the hauls have been observed and sampled.

Foreign

From the 1960s through the early 1970s, foreign trawling enterprises harvested considerable amounts of rockfish off Washington and Oregon, and along with the domestic trawling fleet, landed large quantities of ‘r spp’. Foreign catches of individual species were estimated by Rogers (2003) and attributed to INPFC areas for the years of 1966-1976 for ‘r spp’. The foreign catches were combined across areas for a coastwide removal total.

Discards

abundance-indices

Sub-heading 1

Sub-heading 2

2.1.3 Fishery-Independent Data: possible sources

fishery-independent-data-possible-sources

Northwest Fisheries Science Center (NWFSC) shelf-slope survey

The NWFSC shelf-slope survey is based on a random-grid design; covering the coastal waters from a depth of 55 m to 1,280 m (Bradburn et al. 2011). This design uses four chartered industry vessels in most years, assigned to a roughly equal number of randomly selected grid cells. The survey, which has been conducted from late-May to early-October each year, is divided into two 2-vessel passes of the coast, which are executed from north to south. This design therefore incorporates both vessel-to-vessel differences in catchability as well as variance associated with selecting a relatively small number (~700) of cells from a very large population of possible cells (greater than 11,000) distributed from the Mexican to the Canadian border.

Northwest Fisheries Science Center (NWFSC) slope survey

The NWFSC slope survey covered waters throughout the summer from 183 m to 1280 m north of 34°30' S, which is near Point Conception. The survey strata used to expand the biomass data for this assessment are shown in Table 5.

Alaska Fisheries Science Center (AFSC) slope survey

The AFSC slope survey operated during autumn (October-November) aboard the R/V Miller Freeman. Partial survey coverage of the U.S. west coast occurred during 1988-96 and complete coverage (north of 34°30' S) during 1997, 1999, 2000, and 2001. Only the four years of consistent and complete surveys plus 1996, which surveyed north of 43° N latitude to the U.S.-Canada border, were used in this assessment. The number of tows ranged from 8 in 2001 to 26 in 1996 (Table 7). The numbers of tows with length data for 'r spp' are also shown in Table 7. Because a large number of positive tows occurred in 1996, it was decided to include that year, which surveyed from 43° N latitude to the U.S.-Canada border. Therefore, only tows from 43° N latitude to the U.S.-Canada border were used.

Triennial Bottom Trawl Survey

The triennial survey was first conducted by the AFSC in 1977 and spanned the timeframe from 1977-2004. The survey's design and sampling methods are most recently described in (Weinberg et al. 2002). Its basic design was a series of equally-spaced transects from which searches for tows in a specific depth range were initiated (Figure 5). The survey design has changed slightly over the period of time (Table 4, Figure 3). In general, all of the surveys were conducted in the mid-summer through early fall: the 1977 survey was conducted from early July through late September; the surveys from 1980 through 1989 ran from mid-July to late September; the 1992 survey spanned from mid-July through early October; the 1995 survey was conducted from early June to late August; the 1998 survey ran from early June through early August; and the 2001 and 2004 surveys were conducted in May-July (Figure 4).

Haul depths ranged from 91-457 m during the 1977 survey with no hauls shallower than 91 m. The surveys in 1980, 1983, and 1986 covered the West Coast south to 36.8° N latitude and a depth range of 55-366 meters. The surveys in 1989 and 1992 covered the same depth range but extended the southern range to 34.5° N (near Point Conception). From 1995 through 2004, the surveys covered the depth range 55-500 meters and surveyed south to 34.5° N. In the final year of the triennial series (2004), the NWFSC's Fishery Resource and Monitoring division (FRAM) conducted the survey and followed very similar protocols as the AFSC.

Given the different depths surveyed during 1977, the data from that year were not included in this assessment. Water hauls (Zimmermann et al. 2003) and tows located in Canadian waters were also excluded from the analysis of this survey. The survey was analyzed as an early series (1980-1992) and a late series (1995-2004), as has been done in other West Coast rockfish assessments.

Pacific ocean perch Survey

Pikitch Study

The Pikitch study was conducted between 1985 and 1987 (Pikitch et al. 1988). The northern and southern boundaries of the study were 48°42' N latitude and 42°60' N. latitude respectively,

which is primarily within the Columbia INPFC area (Pikitch et al. 1988 , Rogers and Pikitch 1992). Participation in the study was voluntary and included vessels using bottom, midwater, and shrimp trawl gears.

Observers of normal fishing operations on commercial vessels collected the data, estimated the total weight of the catch by tow and recorded the weight of species retained and discarded in the sample.

2.1.4 Biological Parameters and Data

biological-parameters-and-data

Length And Age Compositions

Include: Sample size information for length and age composition data by area, year, gear, market category, etc., including both the number of trips and fish sampled.

Length compositions were provided from the following sources, by region, with brief descriptions below:

- Commercial fishery - landed: 1966-2016
- Commercial fishery - discard: 2004-2015
- At-sea hake fishery: 2003-2016
- Pacific ocean perch Survey: 1979 and 1985
- Triennial Survey: 1980, 1983, 1986, 1989, 1992, 1995, 1998, 2001, 2004
- AFSC Slope Survey: 1996-2001
- NWFS Slope Survey: 2001-2002
- NWFS Shelf/Slope Survey: 2003-2016

Commercial: PacFIN

Research: NWFS shelf-slope survey

Research: NWFS slope survey

Age Structures

Age structure data were available from the following sources:

Model Region 1

- Source No. 1 (*ex. research, commercial dead fish, live fish, etc.*, date range (ex. 2010-2011))
- Source No. 2 (*ex. research, commercial dead fish, live fish, etc.*, date range (ex. 2010-2011))

- 396 • etc...
- 397 • Begin sublist if desired
 - 398 – Sublist source No. 1
 - 399 – Sublist source No. 2
 - 400 – etc...
- 401 • Back to main list, next Source
- 402 • Last Source

403 Length-at-age was initially estimated external to the population dynamics models using the
 404 von Bertalanffy growth curve, $L_i = L_\infty e^{(-k[t-t_0])}$, where L_i is the length (cm) at age i , t is age
 405 in years, k is rate of increase in growth, t_0 is the intercept, and L_∞ is the asymptotic length.

406 Aging Precision And Bias

407 Weight-Length

408 The weight-length relationship is based on the standard power function: $W = \alpha(L^\beta)$ where
 409 W is individual weight (kg), L is length (cm), and α and β are coefficients used as constants.

410 Maturity And Fecundity

411 Natural Mortality

412 Natural mortality for wild fish populations is extremely difficult to estimate.

413 Sex ratios

434 2. Change No. 2. *Rationale*: blah blah blah.

435 3. Change No. 3. *Rationale*: Continue list as needed.

436 **2.3.2 Definition of Fleets and Areas**

definition-of-fleets-and-areas

437 We generated data sources for each of the models. Fleets by model include:

438 *Commercial*: The commercial fleets include...

439 *Recreational*: The recreational fleets include...

440 *Research*: Research derived-data include...

441 **2.3.3 Summary of Data for Fleets and Areas**
summary-of-data-for-fleets-and-areas

442 **2.3.4 Modeling Software**
modeling-software

443 The STAT team used Stock Synthesis version 3.30.01.13 by Dr. Richard Methot at the
444 NWFSC (Methot and Wetzel 2013). This most recent version was used, since it included
445 improvements and corrections to older versions.

446 **2.3.5 Data Weighting**
data-weighting

447 Citation for Francis method (Francis and Hilborn 2011)
448 Citation for Ianelli-McAllister harmonic mean method (McAllister and Ianelli 1997)

449 **2.3.6 Priors**
priors

450 Citation for Hamel prior on natural mortality (Hamel 2015)

451 **2.3.7 General Model Specifications**
general-model-specifications

452 Citation for posterior predictive fecundity relationship from Dick (2009) and (2017)
453 Model data, control, starter, and forecast files can be found in Appendices A-D.

454 **2.3.8 Estimated And Fixed Parameters**
estimated-and-fixed-parameters

455 A full list of all estimated and fixed parameters is provided in Tables... Estimated and fixed
456 parameters tables currently read in from .csv file, EXAMPLE: Table ??

457 **2.4 Model Selection and Evaluation**
model-selection-and-evaluation

458 **2.4.1 Key Assumptions and Structural Choices**
key-assumptions-and-structural-choices

459 Include: Evidence of search for balance between model realism and parsimony.
460 Comparison of key model assumptions, include comparisons based on nested models (e.g.,
461 asymptotic vs. domed selectivities, constant vs. time-varying selectivities).

2.4.2 Alternate Models Considered

alternate-models-considered

Include: Summary of alternate model configurations that were tried but rejected.

2.4.3 Convergence

convergence

Include: Randomization run results or other evidence of search for global best estimates.

Convergence testing through use of dispersed starting values often requires extreme values to actually explore new areas of the multivariate likelihood surface. Jitter is a SS option that generates random starting values from a normal distribution logistically transformed into each parameter's range (Methot and Wetzel 2013). Table 17 shows the results of running 100 jitters for each pre-STAR base model. . . .

4 Regional Management Considerations

regional-management-considerations

1. For stocks where current practice is to allocate harvests by management area, a recommended method of allocating harvests based on the distribution of biomass should be provided. The MT advisor should be consulted on the appropriate management areas for each stock.
2. Discuss whether a regional management approach makes sense for the species from a biological perspective.
3. If there are insufficient data to analyze a regional management approach, what are the research and data needs to answer this question?

5 Research Needs

research-needs

1. Research need No. 1
2. Research need No. 2
3. Research need No. 3
4. etc.

6 Acknowledgments

acknowledgments
